ABSTRACT

A system communicates with a device in both a wired mode and a wireless mode, and is able to switch between these two modes without permanent disruption to an ongoing use. The system is configured to receive an indication of a condition that suggests switching from the wireless mode of operation to a wired mode of operation, to display a notification for the device to switch, and to transition from the wireless mode of operation to the wired mode of operation.

GAME SYSTEM THAT CONVERTS BETWEEN WIRELESS OPERATION AND WIRED OPERATION WHILE COMMUNICATING WITH A CONTROLLER

RELATED APPLICATIONS

This U.S. Non-provisional Application for Letters Patent is a divisional of and claims the benefit of priority to U.S. patent application Ser. No. 12/748,071, filed Mar. 26, 2010 and issued as U.S. Pat. No. 8,727,882 on May 20, 2014, which is a continuation of and claims the benefit of priority to U.S. patent application Ser. No. 10/769,431, filed Jan. 30, 2004 and issued as U.S. Pat. No. 7,753,788 on Jul. 13, 2010, the disclosure of both being incorporated by reference herein.

TECHNICAL FIELD

This invention relates to peripherals for controlling video games, and more particularly, to game controllers that can be used for both wired and wireless play.

BACKGROUND

Game controllers facilitate user interaction with video games. Game controllers come in many configurations depending upon the desired gaming environment for which the controllers are to be used. There are multi-purpose controllers with one or more multi-function actuators for controlling a wide range of games and specialty controllers designed for specific genre of games, such as steering wheels for racing games, weapons for shooting games, and navigation sticks for aviation games.

Game controllers are designed to connect with the game hosting system using either wireless or wired technologies. For example, wired controllers for PC-based games typically connect to the PC via a serial port, such as a USB port, and wired controllers for console-based gaming systems might use a proprietary interface. Wireless controllers are designed using such technologies as infrared, RF, or Bluetooth.

SUMMARY

A game controller operates in both a wired mode and a wireless mode, and is able to switch between these two modes without permanent disruption to an ongoing game. During a transition from one mode to another, a host gaming system detects when the controller is physically disconnected (for wired mode to wireless mode) or connected (for wireless mode to wired mode). Upon detection, the host gaming system stores the game data and user information and establishes a new communication link with the controller. The host gaming system subsequently reassociates the game data and user information with the game controller as it begins operating in the new mode. This allows the player to continue game play without interruption.

BRIEF DESCRIPTION OF THE CONTENTS

The detailed description is described with reference to the accompanying figures. In the figures, the left-most digit(s) of a reference number identifies the figure in which the reference number first appears. The use of the same reference numbers in different figures indicates similar or identical items.

2

FIG. 1 illustrates a gaming system with a game console and a controller that can operate in both wireless and wired modes.

FIG. 2 is a block diagram of the gaming system.

FIG. 3 is a block diagram of the controller.

FIG. 4 is a flow diagram showing a process for converting use of the controller from wireless operation to wired operation.

FIG. 5 is a flow diagram showing a process for converting use of the controller from wired operation to wireless operation.

DETAILED DESCRIPTION

The following disclosure describes a game controller that can be operated in both a wired mode and a wireless mode. The game controller can switch easily between the two modes without disrupting continued play of the game. For discussion purposes, the game controller is described in the context of a multi-purpose game controller for a console-based gaming system. However, the game controller may be configured in many different ways and with a wide variety of functionality, including specialty controllers.

Gaming System

FIG. 1 shows an exemplary console-based gaming system 100. It includes a game console 102 and up to four controllers, as represented by two controllers 104(1) and 104(2). Each controller 104 is coupled to the game console 102 via a wire or wireless interface and utilizes a suitable data protocol, such as USB (Universal Serial Bus). One controller 104(2) is illustrated as operating in two different modes: a wired mode and a wireless mode. In the wired mode, the controller 104(2) is connected to the game console 102 via a cable 106. The controller derives power from the game console through the cable 106. In the wireless mode, the controller 104(2) is connected to the game console 102 via a wireless link 108. The wireless link may be implemented using any one of many different technologies including, for example, infrared, Bluetooth, or RF technologies. In the wireless mode, the controller 104(2) draws from its own power source, such as a battery. The cable 106 may optionally be detached from the controller to offer more freedom of movement.

The player can switch between wireless operation and wired operation by connecting the serial cable 106 to, or disconnecting it from, the game console 102. Mode-switching may occur during game play without interrupting the game. For example, if a game controller is in wireless mode and the battery runs low during game play, the player may switch to wired mode by plugging the cable 106 into the game console 102 and game play continues without interruption. While in wired mode, the game controller is powered by the game console and the controller battery is recharged.

The game console 102 is equipped with a portable media drive 110 and an optional internal hard disk drive. The portable media drive supports various forms of portable storage media as represented by an optical storage disc 112. Examples of suitable portable storage media include DVD, CD-ROM, game discs, game cartridges, and so forth.

The game console 102 has four slots 114 on its front face to support up to four controllers, although the number and arrangement of slots may be modified. In the wired mode, the game controllers 104 are assigned to the physical slots 114 for controlling various characters/features of the video

game. In wireless mode, however, the game controllers **104(1)-104(4)** are assigned to virtual slots.

In one implementation, virtual slots are assigned, without prompting the user, in sequential order to reduce complexity for the user. Thus, the first virtual slot is assigned to the first wireless game controller introduced to the host game console **102**; the second virtual slot is assigned to the second wireless game controller, and so on. Alternatively, the user can choose a virtual slot via a user interface presented on the display. Actuation of a pre-designated button on the console invokes a slot assignment pane from which the player can select an available virtual slot.

Control buttons **116** are positioned on the front face of the game console **102**. Control buttons **116** include, for example, a power button that switches power to the game console and an eject button that alternately opens and closes a tray of the portable media drive **110** to allow insertion and extraction of the storage disc **112**.

The game console **102** connects to a television or other display (not shown) via A/V interfacing cables **120**. A power cable **122** provides power to the game console. The game console **102** may be further equipped with internal or externally added network capabilities, as represented by the cable or modem connector **124** to facilitate access to a network, such as a local area network (LAN) or the Internet.

Each controller **104** may be equipped with any of a wide variety of user interaction mechanisms. As illustrated in FIG. 1, each controller **104** is equipped with two thumbsticks **132(1)** and **132(2)**, a directional or D-pad **134**, surface buttons **136**, and two triggers **138**. These mechanisms are merely representative, and other known gaming mechanisms (e.g., shoulder buttons) may be substituted for or added to those shown in FIG. 1.

A memory unit (MU) **140** may be inserted into the controller **104** to provide additional and portable storage (as illustrated) or alternatively into the game console **102**. Portable memory units enable users to store game parameters and transport them for play on other consoles. In the illustrated implementation, each controller is configured to accommodate two memory units **140**, although more or less than two units may be employed in other implementations. In other implementations, the game console may support one or more memory units per player.

FIG. 2 shows functional components of the gaming system **100** in more detail. The game console **102** has a central processing unit (CPU) **200** and a memory controller **202** that facilitates processor access to various types of memory, including a flash ROM (Read Only Memory) **204**, a RAM (Random Access Memory) **206**, a hard disk drive **208**, and the portable media drive **106**. The CPU **200** is equipped with a level 1 cache **210** and a level 2 cache **212** to temporarily store data and hence reduce the number of memory access cycles, thereby improving processing speed and throughput.

The CPU **200**, memory controller **202**, and various memory devices are interconnected via one or more buses, including serial and parallel buses, a memory bus, a peripheral bus, and a processor or local bus using any of a variety of bus architectures. By way of example, such architectures can include an Industry Standard Architecture (ISA) bus, a Micro Channel Architecture (MCA) bus, an Enhanced ISA (EISA) bus, a Video Electronics Standards Association (VESA) local bus, and a Peripheral Component Interconnect (PCI) bus.

As one suitable implementation, the CPU **200**, memory controller **202**, ROM **204**, and RAM **206** are integrated onto a common module **214**. ROM **204** is configured as a flash ROM that is connected to the memory controller **202** via a

PCI (Peripheral Component Interconnect) bus and a ROM bus (neither of which are shown). RAM **206** is configured as multiple DDR SDRAM (Double Data Rate Synchronous Dynamic RAM) modules that are independently controlled by the memory controller **202** via separate buses (not shown). The hard disk drive **208** and portable media drive **106** are connected to the memory controller via the PCI bus and an ATA (AT Attachment) bus **216**.

A 3D graphics processing unit **220** and a video encoder **222** form a video processing pipeline for high speed and high resolution graphics processing. Data is carried from the graphics processing unit **220** to the video encoder **222** via a digital video bus (not shown). An audio processing unit **224** and an audio codec (coder/decoder) **226** form a corresponding audio processing pipeline with high fidelity and stereo processing. Audio data is carried between the audio processing unit **224** and the audio codec **226** via a communication link (not shown). The video and audio processing pipelines output data to an A/V (audio/video) port **228** for transmission to the television or other display. In the illustrated implementation, the video and audio processing components **220-228** are mounted on the module **214**.

Also implemented on the module **214** are a USB host controller **230** and a network interface **232**. The USB host controller **230** is coupled to the CPU **200** and the memory controller **202** via a bus (e.g., PCI bus) and serves as host for the peripheral controllers **104(1)-104(4)**. The network interface **232** provides access to a network (e.g., LAN, Internet, etc.) and may be any of a wide variety of various wired or wireless interface components including an Ethernet card, a modem, a Bluetooth module, a cable modem, and the like.

The game console **102** has two dual controller support subassemblies **240(1)** and **240(2)**, with each subassembly supporting up to two of the game controllers **104(1)-104(4)**. A front panel I/O subassembly **242** supports the functionality of the control buttons **116**, as well as any LEDs (light emitting diodes) or other indicators exposed on the outer surface of the game console. A controller wireless interface **244** is also provided to support wireless communication with the game controllers. The wireless interface **244** may use any one of many technologies, including IR, Bluetooth, and RF technologies. The subassemblies **240(1)**, **240(2)**, and **242** and controller wireless interface **244** are coupled to the module **214**, and particularly the USB controller **230**, via one or more cable assemblies **246**.

Eight memory units **140(1)-140(8)** are illustrated as being connectable to the four controllers **104(1)-104(4)**, i.e., two memory units for each controller. Each memory unit **140** offers additional storage on which games, game parameters, and other data may be stored. When inserted into a controller, the memory unit **140** can be accessed by the memory controller **202**. It is noted that, in other implementations, the memory units **140** may be inserted into compatible slots in the game console **102**.

A system power supply module **250** provides power to the components of the gaming system **100** and to the game controllers **104** when operating in the wired mode. A fan **252** cools the circuitry within the game console **102**.

The game console **102** may further implement a cryptography engine to perform common cryptographic functions, such as encryption, decryption, authentication, digital signing, hashing, and the like. The cryptography engine may be implemented as part of the CPU **200**, or in software stored in memory (e.g., ROM **204**, hard disk drive **208**) that executes on the CPU, so that the CPU is configured to perform the cryptographic functions.

Game data **260** generated during game play is stored in memory at the game console, such as in hard disk drive **208** (although other storage may be used). The type and quantity of game data is game specific and can be essentially anything that a game developer would like to track. Examples of game data might include skid marks or fuel level in a racing game, weapon selection or life count in shooter games, and so forth.

The game data **260** is stored in relation to a controller ID **262**. When a player switches between wired and wireless mode of operation, the controller passes in the controller ID and the console tries to match it with any controller IDs stored on hard disk drive **208** in relation to saved game data **260**. If a match is found, the game console reassociates the corresponding game data with the controller.

FIG. **3** shows functional components of the game controller **104** in more detail. The controller **104** has a central processing unit (CPU) **302** and memory, including ROM **304**, RAM **306** and EEPROM **308**. In the illustrated implementation, the CPU **302**, ROM **304**, and RAM **306** are integrated onto a common module **310** and are interconnected via one or more bussing structures. EEPROM **308** is separate from, but interfaced with, the module **310**.

The game controller **104** further includes motor drives **312** to provide tactile feedback to the player and a PWM (pulse width modulation) output **314** to provide the control signals for the motor drives. Player actions received via variable-input actuators **316** (e.g., thumbsticks **132** and triggers **138**) are converted by analog-to-digital converter (ADC) **318** to provide player input to the CPU **302**. ADC **318** can be implemented, for example, as an eight channel 10-bit or 12-bit converter. Other player actions received through dual-state switches **320** (e.g., buttons **136** and D-pad **134**) are passed through I/O **322** to CPU **302**.

As noted above, the game controller **104** supports both wired operation and wireless operation. The game controller **104** includes a USB interface **330** and USB connector **332** for the wired mode of operation. In the illustrated implementation, the game controller **104** is configured to support wireless operation using RF (radio frequency) technologies. An RF module **334** (e.g., 2.4 GHz RF module), a radio baseband unit **336**, and DMA (Direct Memory Access) channels unit **338** support the wireless mode of operation. In other implementations, the game controller can be designed to utilize alternative wireless technologies, such as IR (infrared), Bluetooth, UWB (UltraWide Band), and so forth.

The game controller **104** is equipped with its own power source to enable wireless operation. In the illustrated implementation, a battery **350** supplies power to the electronic modules and components of the game controller **104**. A battery power controller **352** monitors the battery **350** and detects when power is low. Upon detection, a low power condition can be conveyed to the player (e.g., illumination of a light indicator on the controller or display of a warning while the game is being played). The player can then switch to wired mode by plugging in the cable to the game console. The battery power controller **352** also monitors charging behavior of the battery, such as how long it takes to charge and detection of when it is fully charged. In wired mode, the game controller **104** receives power from the game console. A battery charging circuit **354** recharges battery **350** while the controller is connected via the cable. A reset circuit **358** and power on reset circuitry **360** allow the game controller to be reset during operation or when power is initially provided. A power management module **356** generates volt-

ages for the different components on the module **310** and dynamically manages power consumption of those components.

As part of the power management, the console maintains battery life data including, for example, the total life expectancy of the battery, how much power has been drawn during wireless play, and the amount of time left before the battery supply is effectively depleted. The controller sends the battery life data to the console and the console can utilize the data to instruct the player when to switch from wireless play to wired play so that the controller can be recharged. For instance, the console may flash a warning light on the console or present a pop up message on the display to inform the player of low battery conditions and suggest that the player plug the controller cable into the console for continued play.

A voice module **370** may be optionally included in the game controller **104** to receive oral commands or speech from the player. The game controller **104** also has timing components to provide timing functionality, including a general purpose timer **374** (e.g., 16-bit timer), a watchdog timer **376**, an oscillator **378**, and a crystal **380**.

One or more identifiers **390** are stored in EEPROM **308**. In particular, the EEPROM **308** stores a session ID that is used to facilitate switching between wired mode and wireless mode without causing permanent disruption to game play. The session ID includes an active game ID that identifies the current virtual slot being used by the controller and a device ID that identifies the controller itself. After a mode transition occurs (i.e., from wired mode to wireless mode, or vice versa) and a new connection is established, the game controller **104** passes the session ID to the game console. The game console extracts the controller ID portion and looks to match it with any controller ID stored on the game console in relation to saved game data. If a match is found, the game console reassociates the corresponding game data with the controller. In this manner, game play can continue uninterrupted during transition from wireless mode to wired mode.

Mode Switching Operation

FIG. **4** shows a process **400** for switching a game controller from a wireless mode of operation to a wired mode of operation. The process **400** is illustrated as a collection of blocks in a logical flow graph, which represent a sequence of operations that can be implemented in hardware, software, or a combination thereof. In the context of software, the blocks represent computer instructions that, when executed by one or more processors, perform the recited operations.

The process includes operations performed by both the game controller and a host gaming system. For discussion purposes, the process **400** is described with reference to the controller **104** and game console **102** described above with respect to FIGS. **1-3**. It is noted that the process **400** may be implemented by other types of controllers that are designed for both wired and wireless communication, and for other types of gaming systems, such as PCs.

At block **402**, the game controller **104** is operated in a wireless mode. In this mode, the game controller **104** draws power from the battery **350** and transmits user commands via the RF module **334** to the game console **104**. During operation in wireless mode, the game controller **104** monitors for conditions that might suggest a switch in operation from wireless mode to wired mode (block **404**). One example of a condition is where battery power controller

352 detects that battery 350 is running low. Another example condition occurs when a number of packets are lost or otherwise contain incorrect data during the wireless exchange between the controller 104 and console 102, perhaps due to a noisy RF environment or other interference. If no such conditions arise (i.e., the “No” branch from block 404), the game controller remains in wireless mode.

When a transition condition is detected (i.e., the “Yes” branch from block 404), the game controller 104 determines whether the session ID is saved in memory resident at the controller (block 406). The session ID includes an active game ID that identifies the current virtual slot being used by the controller and a device ID that identifies the controller. If the session ID is not saved (i.e., the “No” branch from block 406), the game controller 104 saves the session ID in nonvolatile memory resident at the controller, such as EEPROM 308 (block 408).

Once the session ID is saved on the controller, the host (e.g., game console 102) determines whether the cable 106 is connected to one of the physical slots 114 (block 410). If not (i.e., the “No” branch from block 410), the game controller 104 continues to be operated in wireless mode. It may continue in this mode until the cable is attached or the battery ceases to supply sufficient power. When the cable is connected (i.e., the “Yes” branch from block 410), the game console 102 performs USB enumeration to establish a USB connection via the cable 106 (block 412).

Once the connection is established, the game controller 104 retrieves the session ID from nonvolatile memory and sends it to the game console (block 414). The game console uses the session ID to locate any saved game data and reassociates that game data with the controller (block 416). More particularly, as game data 260 is generated during play, it is stored at the game console 102 in relation to a controller ID 262 associated with the game controller. The controller ID may be unique to the controller itself or it may represent a connection slot currently being used by the controller. When a mode transition occurs (i.e., from wired mode to wireless mode, or vice versa), the game console uses the controller ID from the session ID received from the newly attached game controller and looks to match it with any controller ID stored on the game console. If a match is found, the game console reassociates the game data for the active game identified in the session ID with the controller. In this manner, game play can continue uninterrupted during transition from wireless mode to wired mode. At block 418, the game controller 104 continues in wired mode.

FIG. 5 shows a process 500 for switching a game controller from a wired mode of operation to a wireless mode of operation. The process includes operations performed by both the game controller and a host gaming system, and once again will be described with reference to the controller 104 and game console 102 described above with respect to FIGS. 1-3.

At block 502, the host (e.g., game console 102) performs USB enumeration to establish a USB connection with the game controller 104 via the cable 106. Once a connection is established, the game controller 104 is operated in the wired mode (block 504). At block 506, the game controller 104 determines whether the session ID is saved in controller memory. If the session ID is not saved (i.e., the “No” branch from block 506), the game controller 104 saves the session ID in nonvolatile memory, such as EEPROM 308 (block 508).

Once the session ID is saved on the controller, the game controller 104 determines whether the cable 106 remains connected to one of the physical slots 114 of the game

console (block 510). If it is still connected (i.e., the “Yes” branch from block 510), the game controller 104 continues to be operated in wired mode. When the cable is disconnected (i.e., the “No” branch from block 510), the game controller 104 performs a discovery process to become part of a wireless network and establish a wireless connection between the game controller and the game console (block 512).

Once a wireless connection is established, the game controller 104 retrieves the session ID from its nonvolatile memory and sends it to the game console so that any on-going game data can be reassociated with the controller (block 514). At block 516, the game controller 104 continues to operate in wireless mode.

The described mode switching processes 400 and 500 also accommodate the situation where a new player joins a game. A new player can connect his/her game controller to an available physical slot for wired operation or begin operation directly in wireless mode using the discovery process. The game console first attempts to match the session ID with a current list of session IDs. When a match is not found, the game console associate that device ID with the physical or virtual slot through which it communicates. It can then begin storing game data in relation to that device ID.

CONCLUSION

The above-described game controller facilitates both wired and wireless operation and the ability to switch between wired and wireless operation without interrupting an ongoing game. Although the invention has been described in language specific to structural features and/or methodological acts, it is to be understood that the invention defined in the appended claims is not necessarily limited to the specific features or acts described. Rather, the specific features and acts are disclosed as exemplary forms of implementing the claimed invention.

What is claimed is:

1. A method implemented by a gaming system comprising:
 - receiving, at the gaming system and from a controller, data corresponding to a condition that suggests switching from a wireless mode of operation to a wired mode of operation during use;
 - displaying, at the gaming system, an instruction to switch from the wireless mode of operation to the wired mode of operation;
 - transitioning from the wireless mode of operation to the wired mode of operation;
 - based at least in part on transitioning from the wireless mode of operation to the wired mode of operation, receiving a session identification from the controller; and
 - re-associating the controller with saved data, the saved data being generated during the use before the transitioning from the wireless mode of operation to the wired mode of operation.
2. The method as recited in claim 1, wherein the data corresponding to the condition is based at least in part on a power supply of the controller being low.
3. The method as recited in claim 1, wherein the data corresponding to the condition is based at least in part on a loss of packets transmitted during the use in the wireless mode of operation.
4. The method as recited in claim 1, wherein the data corresponding to the condition is based at least in part on a

determination that packets transmitted during the use in the wireless mode of operation contain incorrect data.

5. The method as recited in claim 1, wherein the instruction comprises a pop up message on a display coupled to the gaming system and the pop up message includes information regarding a low power supply condition of the controller.

6. The method as recited in claim 1, wherein the session identification comprises a controller identifier used by the gaming system to re-associate the controller, currently operating in the wired mode of operation, with the saved data.

7. The method as recited in claim 1, wherein the re-associating distinguishes the saved data from other data generated in association with another controller during the use.

8. A system comprising:

at least one game console configured to:

receive data corresponding to a condition that suggests switching from a wireless mode of operation to a wired mode of operation during use;

cause an instruction to switch from the wireless mode of operation to the wired mode of operation to be output;

transition from the wireless mode of operation to the wired mode of operation;

based at least in part on transitioning from the wireless mode of operation to the wired mode of operation, receive a session identification from a controller in communication with the at least one game console; and

re-associate the controller with saved data, the saved data being generated during the use before the transitioning from the wireless mode of operation to the wired mode of operation.

9. The system as recited in claim 8, wherein the data corresponding to the condition is based at least in part on a power supply of the controller being low.

10. The system as recited in claim 8, wherein the data corresponding to the condition is based at least in part on a loss of packets transmitted during the use in the wireless mode of operation.

11. The system as recited in claim 8, wherein the data corresponding to the condition is based at least in part on a determination that packets transmitted during the use in the wireless mode of operation contain incorrect data.

12. The system as recited in claim 8, wherein the instruction comprises a pop up message on a display coupled to the at least one game console and the pop up message includes information regarding a low power supply condition of the controller.

13. The system as recited in claim 8, wherein the session identification comprises a controller identifier used by the at least one game console to re-associate the controller, currently operating in the wired mode of operation, with the saved data.

14. The system as recited in claim 8, wherein the re-associating distinguishes the saved data from other data generated in association with another controller during the use.

15. A game console comprising:

one or more processors; and

one or more memories storing executable instructions that, when executed on the one or more processors, cause the game console to perform operations comprising:

based at least in part on receiving data corresponding to a condition that suggests switching from a wireless mode of operation to a wired mode of operation during use, causing a switch instruction to be output; transitioning from the wireless mode of operation to the wired mode of operation;

based at least in part on transitioning from the wireless mode of operation to the wired mode of operation, receiving a session identification from a controller; and

re-associating the controller with saved data, the saved data being generated during the use before the transitioning from the wireless mode of operation to the wired mode of operation.

16. The game console as recited in claim 15, wherein the data corresponding to the condition is based at least in part on a power supply of the controller being low.

17. The game console as recited in claim 15, wherein the data corresponding to the condition is based at least in part on a loss of packets transmitted during the use in the wireless mode of operation.

18. The game console as recited in claim 15, wherein the switch instruction comprises a pop up message on a display and the pop up message includes information regarding a low power supply condition of the controller.

19. The game console as recited in claim 15, wherein the session identification comprises a controller identifier used to re-associate the controller, currently operating in the wired mode of operation, with the saved data.

20. The game console as recited in claim 15, wherein the re-associating distinguishes the saved data from other data generated in association with another controller during the use.
